

Training Day – 12

Today's training focused on **GitHub Desktop** and an introduction to **Docker**. The session provided practical experience with graphical Git operations and established the foundational concepts required to understand containerization and application deployment.

Work Undertaken:

- Explored **GitHub Desktop** and learned how to perform common Git operations through a graphical interface instead of relying entirely on terminal commands.
- Practiced the **Git Pull** operation to retrieve the latest changes from a remote repository and synchronize them with the local repository.
- Explored different **GitHub Desktop features** for managing repositories, viewing changes, handling commits, and synchronizing local and remote project states.
- Received an introduction to **Docker** and understood its purpose in packaging and running applications consistently across different systems and environments.
- Learned the basic concepts of **Docker images, containers, and packages** and their roles in containerized application development.
- Understood the difference between a **Docker image** and a **Docker container**.

Additional Learning:

The session helped connect version control practices with modern application deployment workflows. GitHub Desktop provided a more accessible way to manage Git repositories, while Docker introduced the concept of containerization and how it helps reduce differences between development and deployment environments.

Conclusion:

The day provided practical exposure to **GitHub Desktop** and foundational knowledge of **Docker**. Learning repository synchronization alongside the concepts of images and containers established a useful foundation for understanding containerized application development and deployment.
