

Training Day – 17

Today's training focused on understanding **ngrok** and its role in exposing locally running applications to the internet. The session provided practical experience with ngrok setup, domain-based tunneling, and accessing a local project from different devices.

Work Undertaken:

- Learned the fundamentals of **ngrok** and understood how it creates a secure tunnel between a locally running application and the public internet.
- Understood how ngrok provides a **publicly accessible URL/domain** that forwards incoming requests to an application running on the local machine.
- Set up and configured **ngrok** to work with a local project.
- Linked the local project with an **ngrok domain** and successfully made the application accessible through the generated public address.
- Tested the application from **multiple devices** to verify that the locally hosted project could be accessed remotely through the ngrok tunnel.

Additional Learning:

The practical exercise demonstrated how tunneling services can be useful during development and testing. It also provided a better understanding of how locally hosted applications can temporarily be made accessible to external users or devices without directly deploying the application to a public server.

Conclusion:

The day provided practical knowledge of **ngrok and secure tunneling**. Setting up ngrok, connecting a local project to a public domain, and testing the application from different devices improved my understanding of remote access and local application testing.
