

Training Day – 2

Today's training focused on setting up and becoming familiar with the Linux operating system and its command-line environment. The session provided practical experience with system administration basics, shell scripting, remote access, and software installation.

Work Undertaken:

- Successfully installed and configured a Linux virtual machine to create an isolated environment for learning and experimentation.
- Practiced basic Linux commands to understand file-system navigation, file management, directory operations, and terminal usage.
- Created and executed a simple Bash script, gaining an initial understanding of shell scripting and command automation.
- Established SSH connectivity with another machine to understand secure remote access and communication between systems.
- Installed an application on the Linux virtual machine using the system's package manager, gaining familiarity with software installation and package management in Linux.

Additional Learning:

The practical exercises provided a better understanding of how Linux systems are operated through the terminal. Working with Bash, SSH, and package management also introduced essential concepts that are commonly used in server administration, development environments, and cloud-based systems.

Conclusion:

The day was focused on building practical Linux fundamentals. Setting up a virtual machine, using terminal commands, writing a basic Bash script, establishing SSH connectivity, and installing software provided valuable hands-on experience with a Linux-based development environment.
