

## Training Day – 3

Today's training focused on Linux file permissions, ownership, and their importance in web server environments. The session provided practical knowledge of how access to files and directories is controlled and how incorrect configurations can affect website accessibility.

### Work Undertaken:

- Learned the purpose and usage of the **chmod** command for modifying the permissions of files and directories.
- Explored the **chown** command to change the ownership of files and directories.
- Studied the three major Linux permission categories: **Owner, Group, and Others**.
- Understood the Linux permission model based on **read (r), write (w), and execute (x)** permissions and how these permissions control access to files and directories.
- Learned how incorrect file and directory permissions can lead to web server errors such as **403 Forbidden** and **404 Not Found**.
- Studied the purpose and importance of the **index file** in a website directory and how it is commonly used as the default page served by a web server.

### Additional Learning:

The session helped establish a connection between Linux system administration and web server behavior. Understanding permissions, ownership, and default website files is essential when deploying and managing web applications on Linux-based servers.

### Conclusion:

The day provided practical knowledge of Linux access control and website directory structure. Learning commands such as **chmod** and **chown**, along with understanding permissions and index files, improved my ability to troubleshoot common access and web server issues.
