

Training Day – 4

Today's training focused on understanding how web applications communicate with servers and how domain names are connected to web servers. The session also provided practical experience with web deployment, FTP-based file management, and effective techniques for searching information on the internet.

Work Undertaken:

- Learned how data is **read from and written to a server**, gaining a basic understanding of how clients and servers exchange information.
- Understood the relationship between **domain names, name servers, and web servers**. A domain name is associated with a server through DNS and name servers, while communication between the client and server is primarily handled using HTTP.
- Studied **HTTPS** and its importance in modern websites. Learned how HTTPS provides secure communication through encryption and the use of **SSL/TLS certificates**.
- Explored **Vercel** as a web deployment platform, logged in through the terminal using its CLI, and successfully deployed a local project.
- Explored platforms that support the creation of **multiple FTP accounts**, understanding how separate users can be provided with controlled access for server-side file management.

Additional Learning:

- Learned useful **search techniques** for finding specific information on websites, including the use of site:domain queries to restrict search results to a particular domain.
- Explored the concept of **sitemaps** and their usefulness in understanding the structure and publicly available pages of a website.

Conclusion:

The day provided a better understanding of the basic infrastructure behind websites, including servers, domains, DNS, HTTP, and HTTPS. Practical deployment through Vercel and exploration of FTP-based server management further strengthened my understanding of how web applications are deployed and maintained in real-world environments.
