

Training Day – 5

Today's training focused on understanding the **Apache web server** and how it serves web applications to clients. The session provided practical experience with Apache configuration and introduced the concept of virtual hosts for serving specific projects.

Work Undertaken:

- Learned about the role of the **Apache web server** and how it handles client requests and serves web applications and web pages.
- Explored the default Apache configuration, where websites are served from the server's default **document root**.
- Learned how Apache can be configured to serve a specific project based on its **project or domain name**, rather than relying only on the default document root.
- Studied the concept of **Virtual Hosts**, which allows multiple websites or projects to be hosted and configured independently on the same server.
- Configured Apache to create a virtual host for a specific project and associated it with the required project or domain name.
- Created a simple **HTML page** inside the project directory to test the configuration.
- Successfully accessed the HTML page through the configured server, confirming that Apache was correctly serving the intended project.

Additional Learning:

The practical exercise helped me understand how web servers map incoming requests to specific projects and directories. It also provided an introduction to the configuration involved in hosting multiple websites on a single Apache server.

Conclusion:

The day provided valuable hands-on experience with Apache web server configuration. Learning about virtual hosts and successfully serving a project through a custom configuration improved my understanding of how web applications are hosted and accessed on server environments.
